ABSTRACT

Shipboard fires have been the bane of mariners since man's earliest attempts to sail the sea. Understanding the behavior of fire in an enclosed space, such as those found on today's modern seagoing vessels, will greatly enhance the mariner's ability to combat or prevent them. In a joint effort between the Naval Postgraduate School and the University of Notre Dame a computer code has been developed to model a full scale fire in a closed compartment. The code uses a finite volume formulation to obtain numerical solutions to the unsteady, three dimensional conservation equations of mass, momentum and energy. Included are the effects of turbulence, strong buoyancy, surface radiation and wall conduction. The code gives velocities, pressure, temperatures, and densities throughout the field.

This thesis applies that computer code to the U.S. Navy's full scale fire test chamber at Naval Air Warfare Center, China Lake, California. Advanced computer graphics techniques, including color contouring and three dimensional vector field plotting have been applied to make output data more informative. It is hoped that someday this model could provide a useful tool for naval architects in the design of a fire safe ship, and a cost effective means for development evaluation of new firefighting equipment and techniques.

ACKNOWLEDGEMENTS

The author would like to take this opportunity to thank the following persons for their contributions to this work:

To Professor K.T. Yang of the University of Notre Dame, for providing the program FIRE which is central to this work and for making himself available whenever there were questions regarding the code.

To Mr. Kent Farmer of the Naval Air Warfare Center, China Lake, CA for providing the data regarding the fire test chamber.

To Dr. Devadatta Mukutmoni of the Naval Postgraduate School whose assistance with development of the plotting programs and troubleshooting all of the programs was instrumental in completion of this work.

I. INTRODUCTION

A. BACKGROUND

Fire aboard ship is one of the professional mariner's worst fears. With no place to go to escape the heat and smoke the mariner must fight the blaze or face the loss of his vessel. Even though U.S. merchant marine and naval personnel receive some of the best fire fighting training available, annual losses to shipboard fires can easily run into the hundred million dollar range. Ship down time, equipment repair/replacement, personnel injuries and casualties all contribute to these costs and result in the degradation of our merchant marine and naval forces. To minimize these losses it is imperative that the phenomena of fire be studied and understood especially in the relatively closed environment found aboard ship. It is only through study and understanding that adequate means may be developed to prevent or mitigate the devastating effects of a shipboard fire.

Fire is a complex phenomena whose study is equally complex, requiring the combined knowledge of a variety of fields including fluid dynamics, heat and mass transfer, and combustion. Research into the mechanics of fire and development of methods to predict it's behavior will aid engineers in reducing the probability of its ignition and minimizing its effects once ignited. [Ref. 1]

It is the complexity of fire which makes its study so difficult, especially in a shipboard environment. Small scale fire studies have proven inadequate for predicting the behavior of large scale fires. Therefore, full scale studies are generally the only means for conducting realistic experimentation. However, such full scale experimentation can be very costly and dangerous. Shipboard fires often occur in fully enclosed, airtight spaces where pressures can build up during the fire. These spaces may have restricted accesses, contain electronic equipment, flammables and/or toxics, all of which add to the expense and danger of full scale experimentation. Additional costs will also be incurred as air quality and emission standards are stiffened across the country.

To study the phenomena of shipboard fire, the U.S. Navy has built a test facility at the Naval Research Laboratory in Washington, DC known as Fire-1. This facility is essentially a large cylindrical pressure vessel with spherical endcaps intended for use in full scale modeling of fires inside submarines and/or in closed airtight compartments aboard ships. Missile attacks against British warships during the Falklands crisis and the

Iraqi missile attack on the USS STARK in the Persian Gulf in 1987 prompted the U.S. Navy to build a second fire test facility at the Naval Air Warfare Center (NAWC) in China Lake, CA. The purpose of this facility is to study the effects of fire in a vented compartment [Ref. 2, pp. 7-8]. It is this facility which is modeled in this thesis.

A less expensive, and less dangerous alternative to full scale fire experimentation is the use of computer modeling techniques. The development of high speed, high capacity computers has allowed researchers to model thoroughly the complex fire phenomena and predict fire behavior without the expense of full scale testing. A properly developed computer model, validated against actual full scale test data, can provide a less expensive and safe alternative to full scale experimentation. Furthermore, the inherent flexibility of computer modeling allows it to be used on increasingly more complex geometries. Someday this may lead to modeling of entire ships during the design phase to identify areas particularly susceptible to fire, or for the accurate prediction of the effectiveness of new firefighting techniques.

B. COMPUTER MODELING

Field modeling uses finite difference techniques to subdivide the volume being studied, in this case the simulated shipboard compartment, into small, finite volume elements. Using initial conditions specified by the user and the finite difference forms of the equations for conservation of mass, momentum, and energy, values of temperature, pressure, velocity and density are calculated for each of the individual volumetric elements at discrete time intervals. Additional modeling of physical effects such as radiation, turbulence and wall conduction are included to increase the validity of the simulation. The enormous number of calculations necessary for this type of modeling mandates the use of large amounts of computer memory and high speed processors.

The basis for this thesis is provided by a large number of previous research projects. One of the earliest successful models of this type was developed by Aziz and Hellums [Ref. 3] at Rice University in Houston, Texas. They expressed the Navier-Stokes equations in terms of vorticity and vector potential, then solved the resulting three dimensional finite difference equations using a combination of the alternating direction method and successive over-relaxation (SOR). Later work by Mallinson and de Vahl Davis [Ref. 4], Morrison and Tran [Ref. 5]; Chan and Banerjee [Ref. 6]; Ozeo, Fujii, Lior and Churchill [Ref. 7]; and a host of others have all expanded on the use of finite difference techniques to model convective heat transfer in closed compartments.

In the late 1970's and early 1980's, R.G. Rehm and H.R. Baum began developing equations to describe the buoyant flow induced by large scale fires [Refs. 8, 9, 10 and 11] Work done at the University of Notre Dame used a two dimensional finite difference field model to predict velocities, temperatures and smoke concentrations in aircraft cabin fires [Ref. 12 and 13]. The development of a two dimensional model of transient, natural convection cooling was developed, and experimentally verified, by Nicolette *et al* [Ref. 14] using a semi-implicit upwind differencing scheme and global pressure corrections. Still more studies [Refs. 15, 16, 17, 18 , & 19] have utilized finite difference methods to solve non-linear, three dimensional partial differential equations for rectangular enclosures.

C. THE FIRE TEST FACILITY

A full scale test facility has been constructed at the Naval Air Warfare Center (NAWC) at China Lake, CA. This facility, designed to simulate full scale shipboard compartments, consists of three chambers [see Figure 1 on page 4 and Figure 2 on page 5]. The main chamber measures 20 feet by 20 feet by 10 feet and is vented to the atmosphere through an opening in a side wall, in a manner intended to simulate the penetration of a missile or other projectile. The second chamber measures 15 feet by 15 feet by 10 feet is located adjacent to the main chamber to the east, while the third chamber, also measuring 15 feet by 15 feet by 10 feet, is located on top of the main chamber. These secondary chambers are intended to provide a means to study the vertical and horizontal heat transmission rates. [Ref. 2, pp. 7-10]

The entire test structure is constructed of 3/8 inch thick steel bulkheads walls reinforced by 5 inch I-beams on 5 foot centers, and 1/2 inch thick steel decks reinforced underneath by 12 inch I-beams on 5 foot centers. Additional support was provided for the overhead in the main chamber by several 5 inch I-beam columns. These columns were intended to eliminate any sagging and/or distortion of the overhead as it is repeatedly cycled from ambient conditions to the extreme temperatures expected during the missile fuel tests. Access to all three compartments is through hatches which open to the outside of the structure and are kept closed during all testing. There are no openings between any two adjacent chambers. The ventilation opening is located on the north face of the main chamber to simulate an impact hole, such as a missile strike [see Figure 3 on page 6 and Figure 4 on page 7]. [Ref. 2, pp. 10-12]

Instrumentation is provided within the test chamber to measure radiation heat flux, total heat flux, compartment bulk pressure, wall temperatures and compartment gas

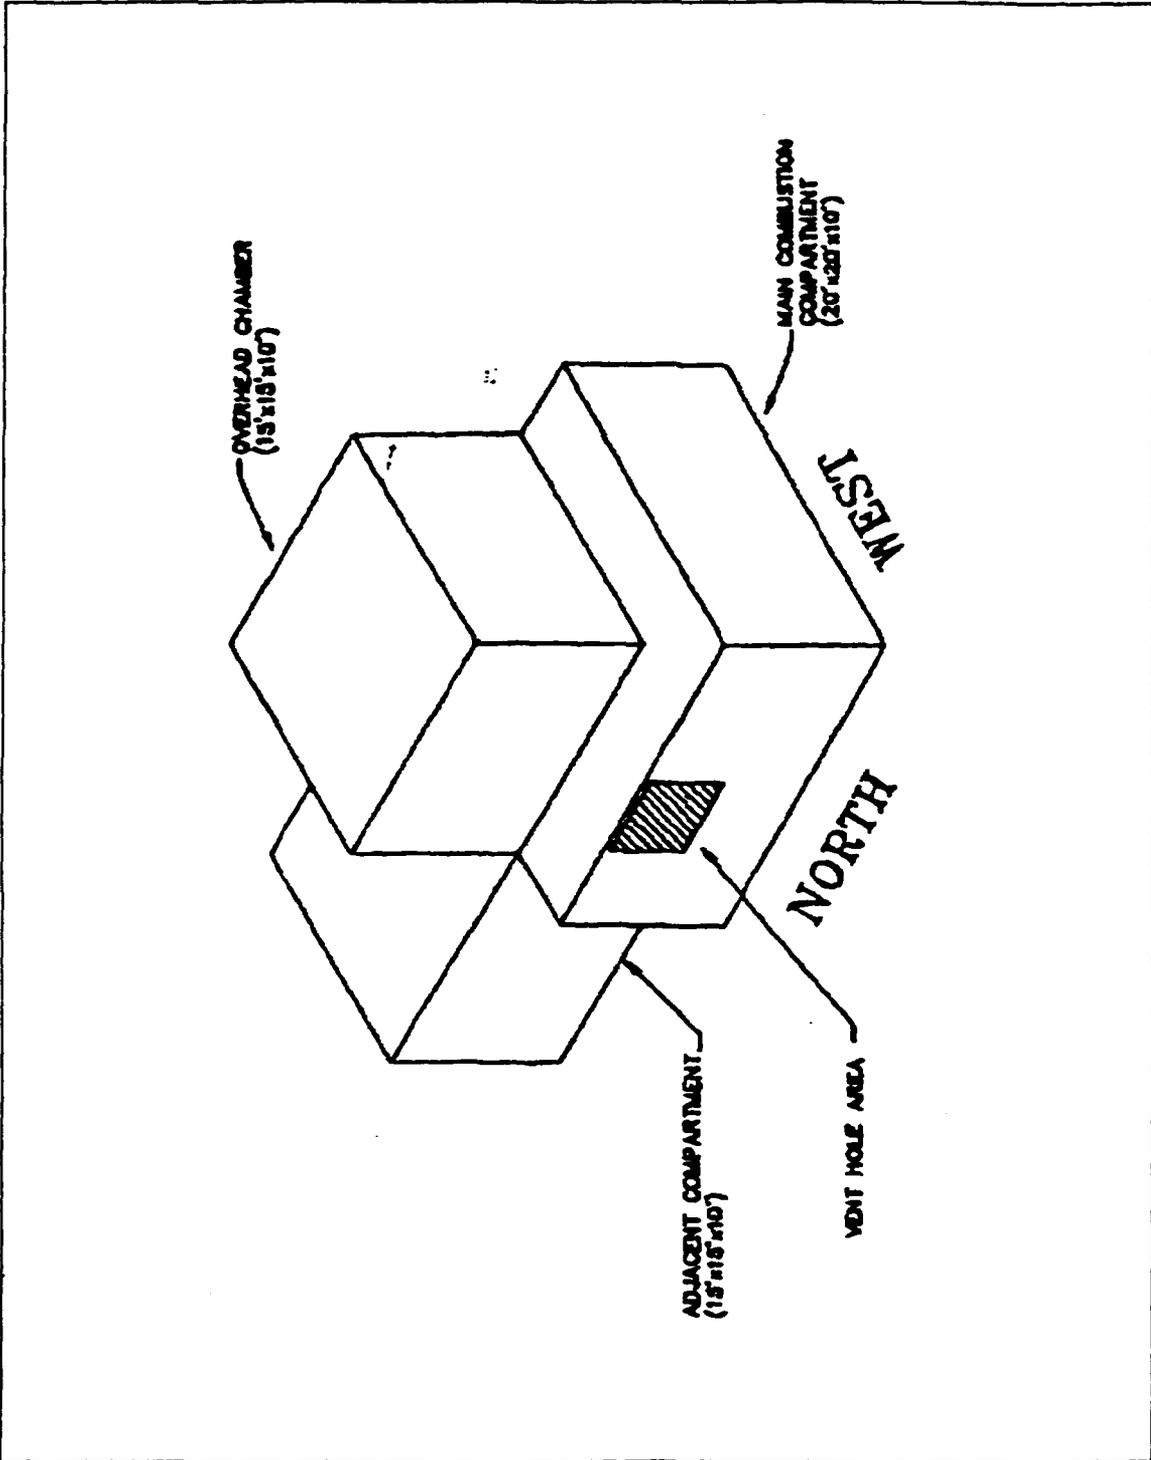

Figure 1. Fire test chamber at NAWC, China Lake, CA.

temperatures. Thermocouples were arranged in vertical arrays of 10 thermocouples. The lowest thermocouple in each array was placed 6 inches above the deck with subsequent thermocouples spaced at 1 foot intervals ending 6 inches below the ceiling [see Figure 5 on page 9]. [Ref. 2, pp. 14-15]

D. THE COMPUTER PROGRAM

This computer model is a joint project undertaken by the Naval Postgraduate School and the University of Notre Dame. It represents a low cost, safe alternative to full scale fire testing. With proper modifications, and properly validated by full scale experimentation, this program should provide a valuable tool for testing the effectiveness of fire mitigation techniques and evaluation of new ship designs.

Work on this program began at Naval Postgraduate School in 1986 when Nies [Ref. 20] used a cartesian coordinate system to model the cylindrical spherical geometry of the FIRE-1 test facility. In 1987 Raycraft [Ref. 21] modified the program to use a cylindrical spherical coordinate system. She also expanded the scope of this project by writing a companion program to calculate view factors and account for surface radiation effects. Using both of Raycraft's programs, Houck [Ref. 22] further expanded the scope of the project to account for the internal ventilation capabilities of the FIRE-1 facility. Most recently, in 1991, McCarthy [Ref. 23] used advanced computer graphics techniques to provide a more accurate pictorial representation of the unique geometry of the FIRE-1 facility and demonstrated the advantages of using full color displays to represent the three dimensional isotherm and velocity vector field profiles. This development greatly enhanced the presentation of the program output. McCarthy was also the first researcher at NPS to incorporate Raycraft's radiation/view factor program as subprograms of the main computer code.

This thesis returns to the cartesian coordinate system used by Nies [Ref. 20], to model the Navy's newest fire test facility at the Naval Air Warfare Center (NAWC) at China Lake, CA. It also advances McCarthy's [Ref. 23] work by applying the enhanced graphics capabilities of the NCAR Graphics software, developed by the National Center for Atmospheric Research [Refs. 24 and 25], for output presentation.

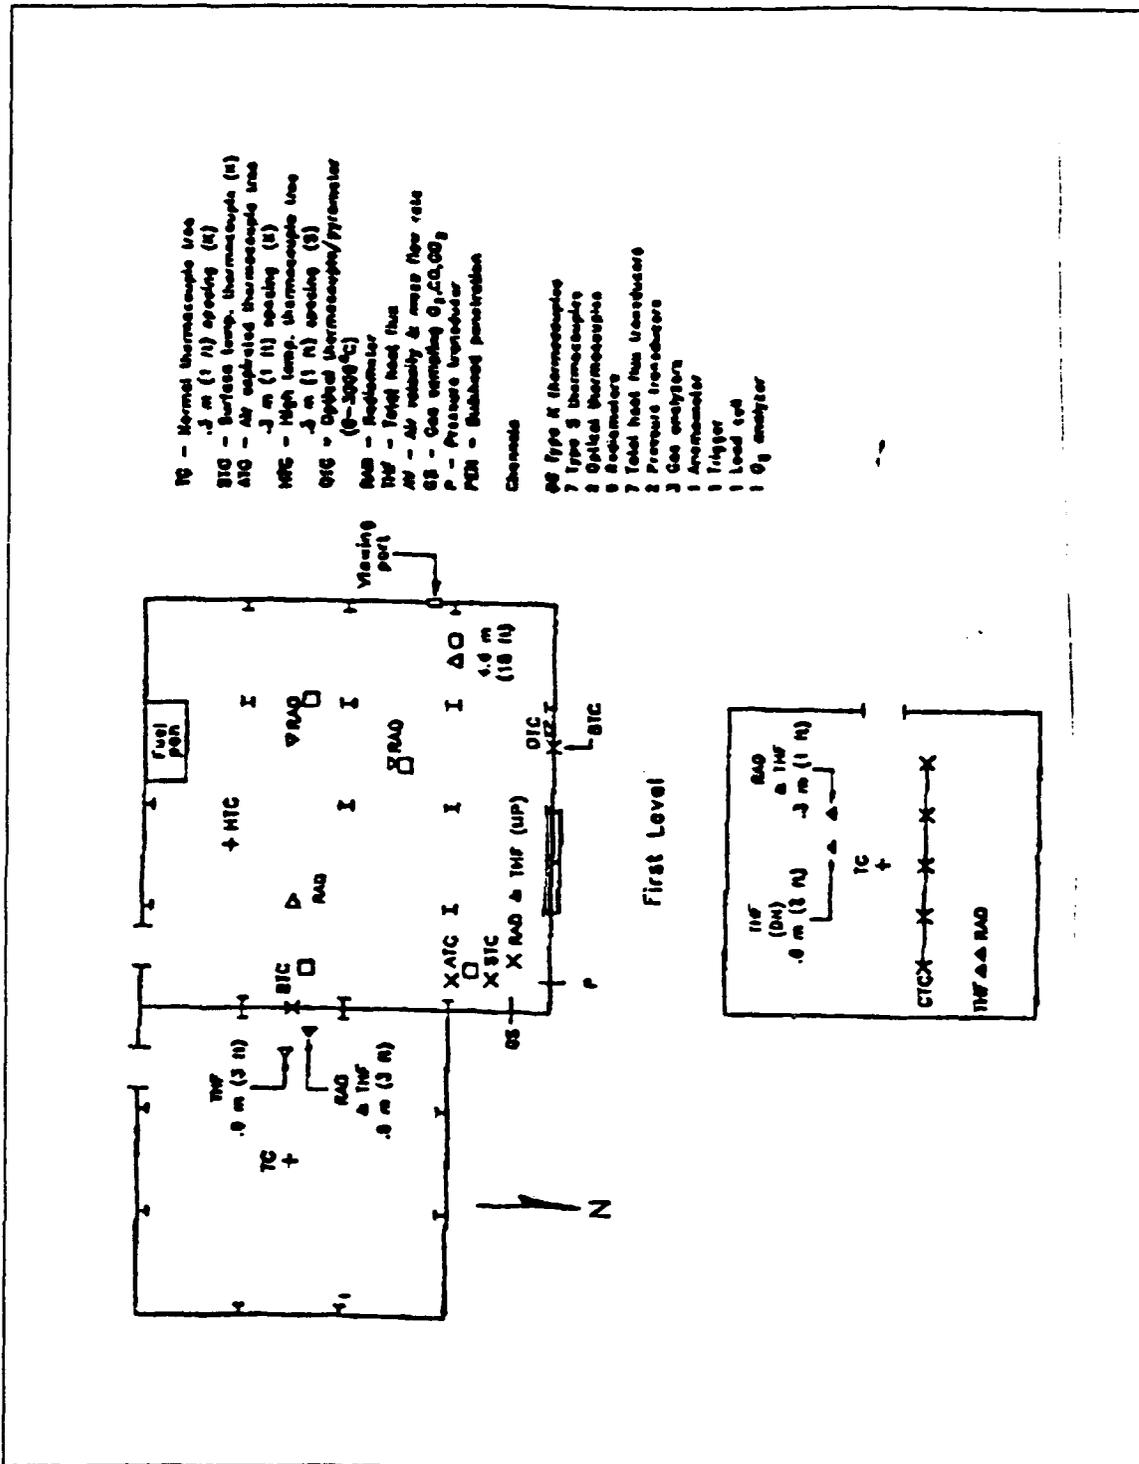

Figure 5. Instrumentation of fire test chamber at NAWC, China Lake, CA.

II. THE NUMERICAL MODEL

A. THE GOVERNING EQUATIONS.

The model used in this code is built on the fundamental laws of conservation of mass (continuity), energy and momentum. One example of these equations is presented by Patankar [Ref. 26, pp. 11-17]. As in that work, this model neglects the pressure work and viscous dissipation terms of the energy equation due to the low flow velocities expected. The volumetric heat generation term will be used to account for heat input by the fire. Patankar's version of the momentum equations [Ref. 26, p. 14, eq. 2.11] included both a body force and an extra viscous force. This model assumes a newtonian fluid therefore the extra viscous force is neglected and the only body force present is due to gravitational effects acting in the negative z-direction. Thus the body force in the z-momentum equation is set equal to $-\rho g$ where g is the local gravitational constant; the negative sign indicates that g is acting in the negative z-direction; and ρ is the fluid density.

Nies [Ref. 20, pp. 16-38] expanded the equations presented by Patankar into the three dimensional, cartesian coordinate system used in this model. Following the development pattern of Doria [Ref. 18, pp. 4-7] and making the assumption that air is a homogeneous gas of constant composition (reactive variations due to the fire are neglected), Nies [Ref. 20, pp. 16-17] incorporated the equations of state for an ideal gas with constant specific heats in the form:

$$P = \rho RT$$

and

$$h = c_p(T - T_{ref})$$

where P , T and ρ represent the bulk pressure, temperature and density inside the control volume, R is the gas constant for air, h is the specific enthalpy, c_p is the specific heat and T_{ref} is a suitably chosen reference temperature.

Again, following the procedures developed by Patankar [Ref. 26] and expanded by Doria [Ref. 18], Nies [Ref. 20, pp. 21-26] goes on to place these six equations in their non-dimensional, integral forms. After subdividing the test chamber into a large, but

finite number of control volumes, finite difference techniques are used to solve for the six unknowns of temperature, pressure, density and the three components of velocity.

B. THE CONTROL VOLUME.

Each control volume, or cell, is defined by the nodal point contained at its center. Values for temperature, density and pressure are calculated at this central point (designated P) and are then assumed to hold for the entire cell. A secondary, or staggered grid system, is used to determine velocities. This staggered grid is offset from the main grid by one half the length of the cell [see Figure 6 on page 12]. As explained in McCarthy [Ref. 23, pp. 18-19] and Patankar [Ref. 26, pp. 115-120], use of this staggered grid alleviates two problems: first, since velocities are dependent upon pressure differentials, the staggered grid allows pressures to be determined at a more frequent interval thereby reducing the error associated with larger separations between nodal points; second, the stagger increases stability by decreasing and, or eliminating unrealistic, oscillatory velocity fields when adjacent velocities are used to satisfy the continuity equation.

Since Patankar's method uses primitive variables, in lieu of the stream function and vorticity, special attention must be paid to the coupling of equations through the pressure terms. An iterative process is used to calculate the pressure in each cell, then a local pressure correction is calculated to ensure that continuity is satisfied. Additional discussions of this correction are included in both Patankar [Ref. 26, pp.120-128] and Doria [Ref. 18, pp. 26-32]. A global pressure correction was described by Nicolette, *et al* [Ref. 14] for addressing net energy changes within the closed compartment. This correction has also been incorporated into this model.

As stated in McCarthy [Ref. 23, p. 19], forcing convergence on a non-linear set of equations, like those describing fluid flow, can be difficult. A variety of schemes have been developed, each with its own set of strengths and weaknesses. This model applies iterative techniques to a solution scheme known as "QUICK", or Quadratic Upstream Interpolation for Convective Kinematics, developed by Leonard [Ref. 19]. With the accuracy of a central differencing scheme and the stability of the convective diffusion terms in upwind differencing, the QUICK scheme estimates values and gradients of the transport variables at the cell faces. The utility of this method was demonstrated by H.Q. Yang [Ref. 27] when he used QUICK to solve the coupled momentum and energy equations for three dimensional flow in a tilted rectangular enclosure.

In addition to the center cell described above, neighboring cells will be used in various computations. To keep track of these cells a standardized nomenclature must be

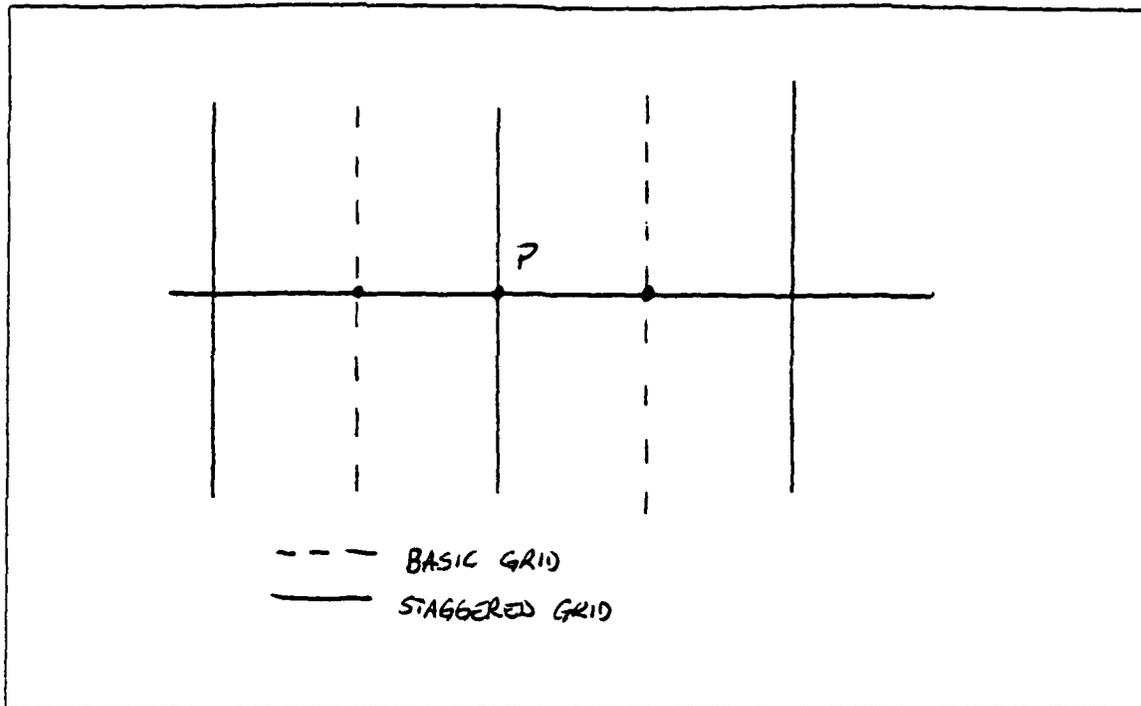

Figure 6. One Dimensional Basic and Staggered Computational Cells.

adopted. Assuming the central cell, cell P, to be located at the point (i,j,k) where i,j and k correspond to the standard coordinated axis x, y and z respectively, then each neighbor may be described as follows (NOTE: the following directions are for standardization of nomenclature only and do not necessarily correspond to compass directions as shown in Figure 1 on page 4):

- East $(i+1,j,k)$
- West $(i-1,j,k)$
- North $(i,j+1,k)$
- South $(i,j-1,k)$
- Front $(i,j,k+1)$
- Back $(i,j,k-1)$

The nodal point in each direction is designated by the capital letter corresponding to the direction (i.e. E, W, N, S, F, B), while the boundary between cell P and its neighbors is designated by a lower case letter corresponding to that direction (i.e. the boundary between cell P and cell N is designated n, and the boundary between P and F is f). A typical cell array on a rectangular grid is shown in figure Figure 7 on page 13.

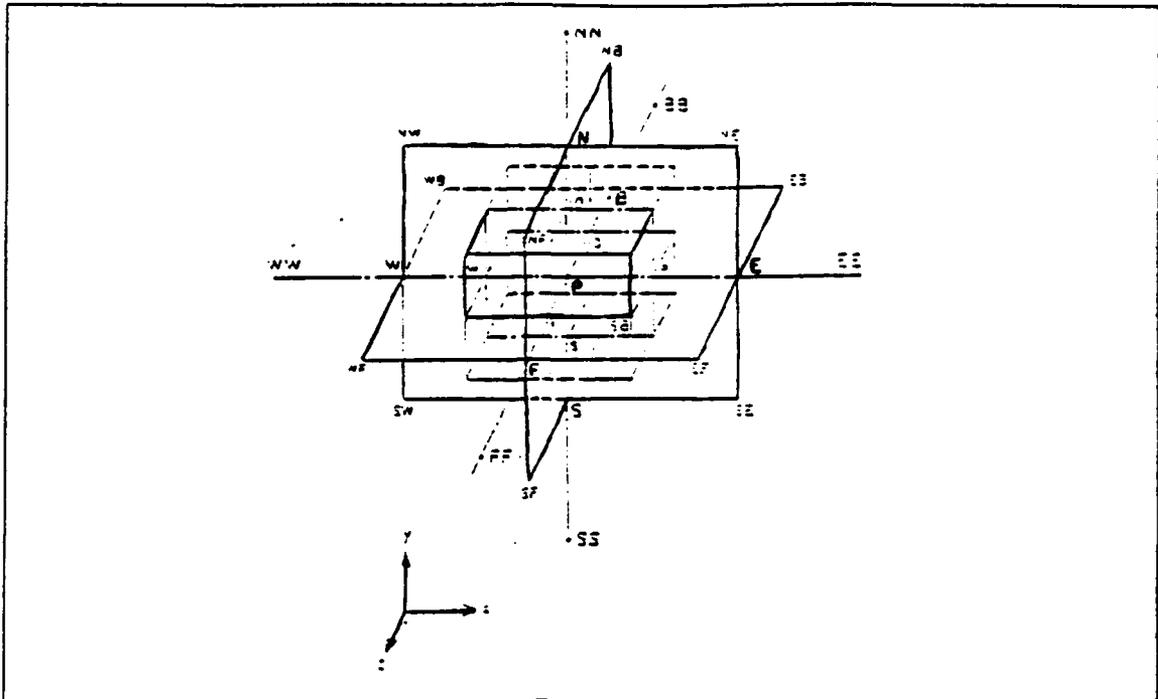

Figure 7. Basic Cell Nomenclature on a Rectangular Grid.

As discussed previously, each P node is used to determine values of density, pressure and temperature which are then applied to its entire cell. Velocities are determined at the cell faces using the staggered grid arrangement described above.

C. DISCRETIZATION OF THE CONSERVATION EQUATIONS.

With that brief background, the integral forms of the conservation equations developed by Nies [Ref. 20, pp. 25-26] may now be discretized. As discussed by Nies [Ref. 20, pp. 26-38] maximum stability and accuracy of the model is achieved by using three different finite differencing schemes. Forward differencing is used for timewise discretization, central differencing is used to discretize the diffusion terms, and the QUICK scheme is used to discretize the convective terms. Use of these techniques to discretize the governing equations was discussed in detail by Nies [Ref. 20, pp. 26-38] and will not be repeated here. The following finite difference forms of the governing equations are taken from his work.

1. The Continuity Equation.

$$(\rho_P - \rho_P^0) \frac{\Delta x \Delta y \Delta z}{\Delta t} + (G_e - G_w) \Delta y \Delta z + (G_n - G_s) \Delta z \Delta x + (G_f - G_b) \Delta x \Delta y = S_{mp}$$

where ρ_p is the density at the current time step; ρ_p^0 is the density at node P at the previous time step; Δt is the incremental time step; Δx , Δy , and Δz are the cell dimensions in the indicated direction; and S_m^e is the residual mass term. The mass flux (G) terms are defined as:

$$G_e = \frac{(\rho_E + \rho_P)}{2} u_e$$

$$G_w = \frac{(\rho_P + \rho_W)}{2} u_w$$

$$G_n = \frac{(\rho_N + \rho_P)}{2} v_n$$

$$G_s = \frac{(\rho_P + \rho_S)}{2} v_s$$

$$G_f = \frac{(\rho_F + \rho_P)}{2} w_f$$

$$G_b = \frac{(\rho_P + \rho_B)}{2} w_b$$

It should be noted that in all of these equations ρ refers to the density; u, v, and w are the three velocity components in the x, y, and z-directions respectively; uppercase subscripts denote values at the indicated nodal point; and lowercase subscripts denote values at cell faces. Also, in order for continuity to be satisfied in this closed system, the residual mass term (S_{mp}) would equal zero. However, due to the approximation inherent in the numerical scheme, we will be satisfied if S_{mp} tends toward zero as determined by comparison to an arbitrarily small threshold value.

2. The Energy Equation.

$$\left[H_{A_P} + \rho_P^0 \frac{\Delta x \Delta y \Delta z}{\Delta t} \right] h_P = H_{A_E} h_E + H_{A_W} h_W + H_{A_N} h_N + H_{A_S} h_S + H_{A_F} h_F + H_{A_B} h_B + H_{S_P}$$

where h is the specific enthalpy at the current time step; h^0 is the specific enthalpy at the previous time step; and the coefficients (H) are defined as:

$$H_{A_E} = \frac{(|G_e| - G_e)}{2} \Delta y \Delta z + \left(\frac{1}{Re_t Pr_t} \right)_e \frac{\Delta y \Delta z}{\Delta x}$$

$$H_{A_w} = \frac{(|G_w| + G_w)}{2} \Delta y \Delta z + \left(\frac{1}{Re_t Pr_t} \right)_w \frac{\Delta y \Delta z}{\Delta x}$$

$$H_{A_n} = \frac{(|G_n| - G_n)}{2} \Delta z \Delta x + \left(\frac{1}{Re_t Pr_t} \right)_n \frac{\Delta z \Delta x}{\Delta y}$$

$$H_{A_s} = \frac{(|G_s| + G_s)}{2} \Delta z \Delta x + \left(\frac{1}{Re_t Pr_t} \right)_s \frac{\Delta z \Delta x}{\Delta y}$$

$$H_{A_f} = \frac{(|G_f| - G_f)}{2} \Delta x \Delta y + \left(\frac{1}{Re_t Pr_t} \right)_f \frac{\Delta x \Delta y}{\Delta z}$$

$$H_{A_b} = \frac{(|G_b| + G_b)}{2} \Delta x \Delta y + \left(\frac{1}{Re_t Pr_t} \right)_b \frac{\Delta x \Delta y}{\Delta z}$$

$$H_{A_p} = H_{A_e} + H_{A_w} + H_{A_n} + H_{A_s} + H_{A_f} + H_{A_b}$$

$$H_{S_p} = \rho_p^0 h_p^0 \Delta x \Delta y \Delta z$$

Also used above are the turbulent Reynolds number (Re_t) and the turbulent Prandtl number (Pr_t). These are defined as

$$Re_t = \frac{\rho_0 u_0 H}{\mu_{eff}}$$

$$Pr_t = \frac{\mu_{eff} c_{p0}}{k_{eff}}$$

where H is the characteristic length (defined as the height of the test chamber in our model); ρ and c_p represent the density and specific heat of air, while the subscript 0 indicates that the properties are to be evaluated at the initial conditions which existed prior to ignition of the fire; u_0 is the reference velocity (set equal to 1.0 ft/sec); and μ_{eff} and k_{eff} are effective values of viscosity and conductivity as defined by Nies [Ref. 20, p. 39-40].

3. The Momentum Equations.

As stated by Nies [Ref. 20, p. 31] the momentum equations are more complex than the previous equations because of the use of the staggered grid and the addition of the shear stress terms. Staggered grids are determined by shifting the main grid one half cell in the negative direction along one axis at a time. Maintaining the nomencla-

ture established for the basic, centered cells, the central node of a cell staggered in the x-direction becomes w, the central node in a cell staggered in the y-direction becomes s, and the central node in a cell staggered in the z-direction becomes b. Likewise, the faces of the staggered cell are designated by the capital letters representing the basic nodes through which they pass. Thus, in the staggered grid P always represents the positive face along the axis where the shift (stagger) is being evaluated. Thus, the x-momentum equation becomes:

$$\left[A_w + \rho_w^0 \frac{\Delta x \Delta y \Delta z}{\Delta t} \right] u_w = A_e u_e + A_{ww} u_{ww} + A_{Nw} u_{Nw} + A_{Sw} u_{Sw} + A_{Fw} u_{Fw} + A_{Bw} u_{Bw} + S_w$$

where

$$A_e = \left[\frac{(|G_p| - G_p)}{2} + \frac{(\frac{1}{Re_t})_p}{\Delta x} \right] \Delta y \Delta z$$

$$A_{ww} = \left[\frac{(|G_{ww}| + G_{ww})}{2} + \frac{(\frac{1}{Re_t})_{ww}}{\Delta x} \right] \Delta y \Delta z$$

$$A_{Nw} = \left[\frac{(|G_{nw}| - G_{nw})}{2} + \frac{(\frac{1}{Re_t})_{nw}}{\Delta y} \right] \Delta z \Delta x$$

$$A_{Sw} = \left[\frac{(|G_{sw}| + G_{sw})}{2} + \frac{(\frac{1}{Re_t})_{sw}}{\Delta y} \right] \Delta z \Delta x$$

$$A_{Fw} = \left[\frac{(|G_{fw}| - G_{fw})}{2} + \frac{(\frac{1}{Re_t})_{fw}}{\Delta z} \right] \Delta x \Delta y$$

$$A_{Bw} = \left[\frac{(|G_{bw}| + G_{bw})}{2} + \frac{(\frac{1}{Re_t})_{bw}}{\Delta z} \right] \Delta x \Delta y$$

$$A_w = A_e + A_{ww} + A_{Nw} + A_{Sw} + A_{Fw} + A_{Bw}$$

$$\begin{aligned}
S_w &= \rho_w^0 u_w^0 \frac{\Delta x \Delta y \Delta z}{\Delta t} - (P_p - P_w) \Delta y \Delta z \\
&+ (u_p - u_{ww}) \left(\frac{1}{Re_t} \right)_p \frac{\Delta y \Delta z}{\Delta x} - (u_{ww} - u_{ww}) \left(\frac{1}{Re_t} \right)_{ww} \frac{\Delta y \Delta z}{\Delta x} \\
&+ \left[(v_{nw} - v_{nww}) \left(\frac{1}{Re_t} \right)_{nw} - (v_w - v_{ww}) \left(\frac{1}{Re_t} \right)_{sw} \right] \Delta z \\
&+ \left[(w_{wf} - w_{wwf}) \left(\frac{1}{Re_t} \right)_{wf} - (w_w - w_{ww}) \left(\frac{1}{Re_t} \right)_{bw} \right] \Delta y
\end{aligned}$$

and

$$\rho_w^0 = \frac{\rho_p^0 + \rho_w^0}{2}$$

$$u_p = \frac{u_e + u_w}{2}$$

$$u_{ww} = \frac{u_w + u_{nw}}{2}$$

$$u_{nw} = \frac{u_{nw} + u_w}{2}$$

$$u_{sw} = \frac{u_{sw} + u_w}{2}$$

$$u_{fw} = \frac{u_{fw} + u_w}{2}$$

$$u_{bw} = \frac{u_{bw} + u_w}{2}$$

$$G_p = \rho_p u_p$$

$$G_w = \rho_w u_w$$

$$G_{nw} = \frac{\left[\frac{\rho_n + \rho_p}{2} v_n + \frac{\rho_{nw} + \rho_w}{2} v_{nw} \right]}{2}$$

$$G_{sw} = \frac{\left[\frac{\rho^P + \rho_S}{2} v_s + \frac{\rho_W + \rho_{SW}}{2} v_{sw} \right]}{2}$$

$$G_{fw} = \frac{\left[\frac{\rho_F + \rho_P}{2} w_f + \frac{\rho_{FW} + \rho_W}{2} w_{fw} \right]}{2}$$

$$G_{bw} = \frac{\left[\frac{\rho_P + \rho_B}{2} w_b + \frac{\rho_W + \rho_{BW}}{2} w_{bw} \right]}{2}$$

Development of the equations for y and z-momentum proceed in a similar fashion and will not be repeated here in the interest of brevity.

D. PRESSURE CORRECTIONS.

1. Global Pressure Corrections.

As described by Nies [Ref. 20, pp. 50-52] and McCarthy [Ref. 23, pp.47-48], in a fixed mass - fixed volume system, overall pressure depends on the net energy added or removed from the system. Nicolette, *et al*, [Ref. 14] demonstrated that in such a system, with a uniform grid, the sum of the product of density times volume for all of the cells remains fixed at the total mass of the system. Therefore, at any time during the fire, the total mass of the system must equal the initial mass at the equilibrium density which existed before the fire was ignited. This may be expressed as:

$$\sum_i \rho_i^n (\Delta x \Delta y \Delta z)_i = \sum_i \rho_{EQ,i} (\Delta x \Delta y \Delta z)_i$$

Since the grid is uniform, the term $(\Delta x \Delta y \Delta z)_i$ is a constant, independent of time, it may be divided out of both sides of the equation leaving:

$$\sum_i \rho_i^n = \sum_i \rho_{EQ,i}$$

Now, since we are operating under the assumption that the fluid inside our burn chamber is an ideal gas, and recalling that we are also working in a fixed volume environment, the density (ρ) may now be expressed as a function of pressure and temperature only.

$$\rho_i = f(P, T)_i$$

The actual pressures and temperatures may now be expressed as the sum of an estimated value (P^* and T^*) and a global correction (P_g and T_g).

$$P = P^* + P_g$$

$$T = T^* + T_g$$

Now applying the ideal gas law and substituting into the summation relation shown above, we can solve for the global pressure correction as

$$P_g = \frac{\sum_i P_{EQ} \left(\frac{1}{T_i} - \frac{1}{T^*} \right) - \sum_i \frac{P^*}{T^*}}{\sum_i \frac{1}{T^*}}$$

This relation is then iterated until a global pressure correction is obtained which conserves mass for all the cells.

2. Local Pressure Corrections.

As explained by both McCarthy [Ref. 23, pp.49-51] and Nies [Ref. 20, pp. 52-54], the method for obtaining the local pressure correction was developed by Patankar [Ref. 26, pp. 120-126] and Doria [Ref. 18, pp. 26-32] and is similar to the method used for determination of the global pressure correction. For this correction, the pressure distribution found during the previous time step is used to estimate the velocity field. Continuity is then applied and residual mass terms (S_{mp}) are calculated for each cell. Based on these residual mass terms a pressure correction is estimated and the process is repeated until the values of S_{mp} fall below a previously established threshold value at which point the final value of the correction is now known. As in the determination of the global pressure correction, the total pressure is expressed as the sum of the estimated pressure and the local correction.

$$P = P^x + P'$$

where P is the total pressure, P^x is the estimated pressure, and P' is the local pressure correction. The local pressure correction may now be expressed in its finite difference form

$$A_P P'_P = A_E P'_E + A_W P'_W + A_N P'_N + A_S P'_S + A_F P'_F + A_B P'_B - S_{mp} \Delta x \Delta y \Delta z$$

where

$$A_E = \frac{\rho_e (\Delta y \Delta z)^2}{A_e + \rho_e \frac{\Delta x \Delta y \Delta z}{\Delta t}}$$

$$A_W = \frac{\rho_w (\Delta y \Delta z)^2}{A_w + \rho_w \frac{\Delta x \Delta y \Delta z}{\Delta t}}$$

$$A_N = \frac{\rho_n (\Delta z \Delta x)^2}{A_n + \rho_n \frac{\Delta x \Delta y \Delta z}{\Delta t}}$$

$$A_S = \frac{\rho_s (\Delta z \Delta x)^2}{A_s + \rho_s \frac{\Delta x \Delta y \Delta z}{\Delta t}}$$

$$A_F = \frac{\rho_f (\Delta x \Delta y)^2}{A_f + \rho_f \frac{\Delta x \Delta y \Delta z}{\Delta t}}$$

$$A_B = \frac{\rho_b (\Delta x \Delta y)^2}{A_b + \rho_b \frac{\Delta x \Delta y \Delta z}{\Delta t}}$$

$$A_P = A_E + A_W + A_N + A_S + A_F + A_B$$

At solid boundaries where the mass flux (G) is zero, the appropriate coefficient (A) corresponding to that boundary is also set equal to zero.

After the local pressure correction (P') is determined, new velocities are determined from the following relations:

$$u = u^x + u'$$

$$v = v^x + v'$$

$$w = w^x + w'$$

where

$$u' = \frac{(P'_p - P'_w)\Delta y\Delta z}{A_w + \rho_w \frac{\Delta x\Delta y\Delta z}{\Delta t}}$$

$$v' = \frac{(P'_p - P'_s)\Delta z\Delta x}{A_s + \rho_s \frac{\Delta x\Delta y\Delta z}{\Delta t}}$$

$$w' = \frac{(P'_p - P'_b)\Delta x\Delta y}{A_b + \rho_b \frac{\Delta x\Delta y\Delta z}{\Delta t}}$$

The residual mass (S_{mp}) is again compared to the threshold value and the entire process is iterated if necessary.

E. INITIAL AND BOUNDARY CONDITIONS.

Before this system of equations can be solved, appropriate initial and boundary conditions must be determined and applied. As in the previous work conducted by Nies, Raycraft, Houck and McCarthy [Refs. 20, 21, 22, and 23], these conditions are established as follows:

1. Initial Conditions.

The initial conditions for the model are determined by the conditions existing inside the test chamber just prior to starting the fire. It is assumed that the air is uniformly at rest, thus all components of velocity are set equal to zero throughout the chamber. The temperature inside the chamber is assumed to be uniform and equal to the ambient temperature outside the chamber, therefore the non-dimensional temperature field is set equal to 1.0 throughout the model. Finally, pressure and density are also assumed to be uniformly distributed and in static equilibrium.

2. Boundary Conditions.

The chamber walls are constructed of standard 3/8 inch sheet steel [Ref. 2, p. 10], therefore they are presumed to be non-porous. This allows all velocity components

to be set equal to zero at the wall (the so called "no slip" condition), and the mass flux across the wall is also set to zero (the "impermeable wall" condition). Since there is no heat generation inside the walls of the chamber, it can be assumed that no discontinuities exist between the temperature of the surface of the wall and the air immediately adjacent to it. Therefore the inside surface temperature of the wall must be identically equal to the temperature of the fluid immediately adjacent to it. These condition may be expressed as follows:

$$u_{surf} = 0$$

$$v_{surf} = 0$$

$$w_{surf} = 0$$

$$T_{surf} = T_{air}$$

Finally, conservation of energy must also be satisfied at the wall. Therefore

$$q_r - k_{air} \frac{\delta T_{air}}{\delta n} = -k_{surf} \frac{\delta T_{surf}}{\delta n}$$

where n represents the inward pointing normal at that location; and q_r represents the energy transfer due to thermal radiation.

F. MODELING OF PHYSICAL PHENOMENA.

1. Wall Conduction.

Heat losses through the walls are calculated assuming one dimensional, unsteady heat conduction through walls of uniform conductivity. A constant convective heat transfer condition is assumed to exist between the exterior of the wall and the environment.

2. Turbulence.

As explained by McCarthy [Ref. 23, pp. 15-16] and Nies [Ref. 20, pp. 39-40] the turbulence model used in this code is a simple algebraic model first developed by Nee and Liu [Ref. 28]. This model calculates an effective viscosity (μ_{eff}) and an effective conductivity (k_{eff}) for recirculating buoyant flows with widely fluctuating turbulence levels. Development of these equations, as used in this model, is shown in Nies [Ref. 20, p. 39-40].

3. Radiation.

The radiation model used in this code considers only surface radiation while considering the gas and smoke to be transparent. Developed and explained in detail by Raycraft [Ref. 21], the model is based on the net radiosity method discussed by Sparrow and Cess [Ref. 29]. As summarized by McCarthy [Ref. 23, p. 17], the model treats both the chamber walls and the flame areas as grey, diffuse surfaces.

III. THE COMPUTER PROGRAMS

A. INTRODUCTION.

Running the computer code for this project, from initial data input to final graphical output, is a three step process. Initial input is accomplished using the program FIREBLD; numerical data output is generated by the program FIRE; and final graphical output is provided by the programs ISOTHERM and VELOCITY, both of which are written to utilize the graphics software developed by the National Center for Atmospheric Research (NCAR).

B. PROGRAM FIREBLD.

Program FIREBLD [Appendix A] is used to build and or modify the data file FIRE.DATA which provides the input data required to run the main code, FIRE. Originally part of SUBROUTINE INPUT in FIRE, FIREBLD represents an effort to improve the "user friendliness" of the code. It accomplishes this by creating an interactive input environment which attempts to minimize the user's need for detailed knowledge of the internal operation of FIRE. As the user friendliness of the SUBROUTINE INPUT increased, so did its length. It quickly became the largest subroutine in FIRE, and in an effort to streamline that code, it was converted into a separate program. This conversion had two advantageous effects:

1. It increased the run time options for FIRE by eliminating the need for direct operator input while running the program. This allows FIRE to take advantage of the time savings associated with running in background and or batch modes; and
2. Elimination of the necessity for direct operator input has reduced the total run time of the code (FIRE) by placing the slow process of data input in a separate program.

FIREBLD is designed to query the user regarding the various input parameters, indicating the proper units when appropriate. It begins by looking for a previously created input file. If one is found the user is asked if it should be used, a negative response causes program termination, while a positive response causes the data file to be read. The program then continues by displaying the existing data and asking the user if any changes are desired. If a previously created input file is not located, FIREBLD automatically enters input mode and prompts the user for the required information.

Some of the input data used in this project is shown in Table 1 on page 25 and Table 2 on page 26. Additional data which may be input at the user's discretion includes:

Thermocouple data, including number and location. The present code is limited to a maximum of 20 thermocouples, but this may be changed with only minor modifications to the code.

Mass source data, including location and size. This portion of the code was not required for this project and therefore has not been tested.

Internal solids data, including location, size, conductivity, specific heat, and fan speed. The fan speed included here is for internal ventilation contained wholly inside the test chamber. This is similar to the ventilation incorporated into the code by Houck [Ref. 22]. The problems experienced by McCarthy [Ref. 23] in association with this ventilation, have not been seen here. It should also be noted that the external chamber walls are input as internal solids.

Table 1. INPUT DATA

	Directions		
	X	Y	Z
Chamber dimensions			
Length (feet)	20.0	20.0	10.0
Wall thickness (inches)	0.375		
Floor ceiling thickness (inches)	0.5		
Number of Computational Cells			
Inside the chamber	20	20	10
Total number of cells	24	24	14
Fire location			
Starting node	19	4	0
Ending node	20	8	1
Times (seconds)			
Total length of run	90.0		
Incremental time step	0.003125		
Between data saves	30.0		
Between data saves for plotting	30.0		
Fire start time	0.0		

Table 2. WALL DATA: The following data is input through FIREBLD to identify the location of the chamber walls.

	Location		
	X	Y	Z
Wall #1, starting node	0	0	0
Wall #1, number of nodes	1	21	11
Wall #2, starting node	0	0	0
Wall #2, number of nodes	21	1	11
Wall #3 (floor), starting node	0	0	0
Wall #3, number of nodes	21	21	1
Wall #4 (ceiling), starting node	0	0	11
Wall #4, number of nodes	21	21	11
Wall #5, starting node	0	21	0
Wall #5, number of nodes	21	1	11
Wall #6, starting node	21	0	0
Wall #6, number of nodes	1	21	11

C. PROGRAM FIRE.

Operational details of the main program FIRE [Appendix B] are provided by McCarthy [Ref. 23, pp. 55-56]. The only significant difference between his version of the program and the present version (neglecting the obvious difference of compartment geometry) is that the separate program required by McCarthy for the generation of view factors, is incorporated into the present code as a subroutine, SUBROUTINE VIEW. Also, the present code inputs the wall locations and properties as "internal solids", as noted above.

Heat input from the fire is modeled as a volumetric heat source based on the dimensions of the fire as provided by FIREBLD. The magnitude of this heat source is calculated in SUBROUTINE CALQ. It is based on the known heat of combustion of the fuel used (2600 Btu/lbm, as provided by NAWC, China Lake, CA) and an estimated burn rate of 1.0 lbm/sec. However, due to temperature and velocity instabilities associated with this high heat generation rate, it was necessary to reduce the burn rate by two

orders of magnitude to 0.01 lbm/sec in order to achieve stable output data. Increasing the burn rate to its proper level would necessitate reductions in the time step used, and require multiple data runs to confirm stable output. Due to time restrictions placed on completion of this work, those additional data runs were left for later investigators.

In making comparisons to McCarthy's work [Ref. 23, p. 55], it is interesting to note that he used the VAXSTATION 3100 which required approximately 3600 seconds of CPU time to process one second of fire time. The current work required approximately 677 seconds of CPU time per second of fire time, utilizing the AMDAHL #### mainframe processor here at Naval Postgraduate School. Even when performance is broken down further, to a CPU seconds per fire second per cell basis, the AMDAHL out performs the VAX by a 5.5 or 6 to 1 margin. Although no attempt was made to determine the source of this improvement, the majority of it can be attributed to the increased clock speed of the AMDAHL machine, which unconfirmed estimates place at approximately 4 to 1 over the VAX.

D. GRAPHICAL ANALYSIS.

The value of graphical analysis was successfully demonstrated by McCarthy [Ref. 23]. This work utilizes a different graphics software package in order to standardize the software used at both Naval Postgraduate School and the University of Notre Dame. The software package chosen, NCAR Graphics, was created at the National Center for Atmospheric Research (NCAR) and is intended specifically for scientific applications. The primary advantage of NCAR over the previously used graphics software is in the flexibility of output presentation built in to the NCAR software.

The two graphics program used in the present study, ISOTHERM [Appendix C] and VELOCITY [Appendix D] each utilize the three dimensional PLOT.DATA file created by FIRE to generate two dimensional temperature and velocity profiles as requested by the user. Each program allows the user to specify the desired two dimensional view (or section) (i.e. Plan view, X-Z profile, or Y-Z profile) and the location (or elevation) in the third dimension where that section is to be taken. Each program then performs two linear interpolations, the first to locate the requested section, and the second to convert the grid used by FIRE to a uniform grid as required by the NCAR Graphics software.

Scaling of the output in each program is accomplished in different manners. VELOCITY sets the maximum vector size in any given plot by the maximum interpolated velocity for that section (NOTE: velocities are shown in centimeters per second). While the color scale used in each plot generated by ISOTHERM is determined by dividing the

range from ambient ($70^{\circ} \text{F} = 21.1^{\circ} \text{C}$) to the maximum temperature in the non-interpolated data into 14 color zones. These scaling techniques are examples of the flexibility of the NCAR Graphics software, and each user may customize the output to satisfy the current needs desires with minimal effort.

Color isotherm graphics are printed on a DEC LJ250 Companion Color printer using ink jet technology, attached to a VAXStation 3100 M38 standalone workstation. Velocity profiles are printed on a DEC LN03 Laser printer attached to the VAX cluster in the Mechanical Engineering Department at the Naval Postgraduate School. The following figures [Figure 8 on page 29 through Figure 25 on page 46] show the temperature and velocity profiles for each of the available view planes at 30, 60 and 90 seconds of fire time. Elevations are shown on each figure and were chosen to provide a plan view at mid-compartment height and profiles through the fire. Also included in both ISOTHERM and VELOCITY is the option to "zoom" in on any localized region of the plot as desired by the user. Figure 26 on page 47 and Figure 27 on page 48 demonstrate this capability. Note also, that the axis on all of these plots are marked (in feet) to indicate the section being viewed.

IV. CONCLUSIONS AND RECOMMENDATIONS

A. CONCLUSIONS.

1. Program FIREBLD represents a marked improvement in user friendly data input to FIRE.
2. Additional improvements can be made in user friendliness of FIREBLD, and thus FIRE. Specifically, all locations and dimensions should be input as length measurements (i.e. feet or meters) by the user.
3. The burn rate used by SUBROUTINE CALQ in program FIRE is artificially low and must be increased before the code can be properly validated against actual test data.
4. The NCAR Graphics software provides increased flexibility in graphics output over the previously used graphics package.
5. The temperature and velocity profiles generated by this work appear to have the expected characteristics of an actual fire. Further testing and comparison to actual test data is necessary for validation of the code.
6. The ink jet printer used to create hard copy graphical printouts of the data in this work is slow and of marginal quality for professional publication. Improved graphics printing capabilities should be pursued.

B. RECOMMENDATIONS.

1. Increase user friendliness of FIREBLD by putting all input in terms easily determined by the user. Specifically:
 - Input locations in terms of length measurements vice nodal locations.
 - User should have his choice of units (SI or English) when inputting data.
 - Input data should not require any manipulation by the user prior to entry.
2. Increase the burn rate used by SUBROUTINE CALQ in program FIRE to realistic levels and adjust size of time step as necessary to achieve stability.
3. Expand FIRE to completely model test chamber at the Naval Air Warfare Center, China Lake, CA. Specifically, include the natural vent and adjacent compartments.
4. Validate model against actual test procedures and results from Naval Air Warfare Center, China Lake.
5. Examine alternative graphical presentation schemes available with the NCAR Graphics software. Specifically, test feasibility of combining isotherm and velocity plots into single output. Also, examine use of NCAR Graphics movie making capabilities to provide a "real time" representation of data.
6. Enhance clarity of graphics printouts by procuring access to a laser quality color printing.

APPENDIX C. PROGRAM ISOTHERM

This program generates two dimensional isotherm plots using the National Center for Atmospheric Research (NCAR) Graphics software, from three dimensional temperature field data produced by program FIRE.

```
PROGRAM ISOTHERM
*****
*
* This program uses NCAR GRAPHICS to calculate and plot isotherms in
* an arbitrary two dimensional section with uniform grid spacing
* from a non-uniform three dimensional grid using linear interpola-
* tion routines. Isotherms are plotted using 14 equal size color
* ranges based on the maximum temperature in the 3-D grid.
*
*****
*Variables used in this program. Arrays names are followed by left and
* right parenthesis (). (NOTE: some variables used in the plotting
* routines have been specifically omitted from this list)
*
* bth      : Non-dimensional compartment breadth (X-direction)
* cx-     : Interpolation parameter used to generate 2-D grid
* cy      : Interpolation parameter used to generate 2-D grid
* c1      : Interpolation parameter used to locate desired 3-D section
* c2      : Interpolation parameter used to locate desired 3-D section
* c11     : Interpolation parameter used to generate 2-D grid
* c12     : Interpolation parameter used to generate 2-D grid
* c21     : Interpolation parameter used to generate 2-D grid
* c22     : Interpolation parameter used to generate 2-D grid
* dx      : Non-dimensional 3-D grid size inside compartment, X dir.
*          : (redefined in SUBROUTINE SCTN as non-dimensional uniform
*          : grid spacing in the X direction for the 2-D plot)
* dy      : Non-dimensional 3-D grid size inside compartment, Y dir.
*          : (redefined in SUBROUTINE SCTN as non-dimensional uniform
*          : grid spacing in the Y direction for the 2-D plot)
* dz      : Non-dimensional 3-D grid size inside compartment, Z dir.
* h       : Non-dimensional Z length of compartment to model
* iplot   : Number of grids in X direction of 2-D grid
* iscn    : If >0 hold X constant, else =0
* ix      : Number of X grid points in "xxs" array
* jplot   : Number of grids in Y direction of 2-D grid
* jscn    : If >0 hold Y constant, else =0
* jyy     : Number of Y grid points in "yys" array
* kscn    : If >0 hold Z constant, else =0
* ncrmax  : Maximum number of contours
* ni      : Number of cells across compartment, X dir.
* nj      : Number of cells across compartment, Y dir.
* nk      : Number of cells across compartment, Z dir.
* nstop   : Control variable to terminate program
```

```

* nview : Input value of desired plot (from SUBROUTINE SECTION)
* t()   : Imported array of temperature values
* ta    : Ambient absolute temperature prior to fire ignition
* temp() : Temperatures of desired section of 3-D grid
* tflr  : Non-dimensional thickness of compartment floor/ceiling
* time  : Dimensional time (in seconds) since fire ignition
* tmax  : Maximum temperature in "temp" array (redefined in SUBROUTINE
*        SECTION as maximum temperature in interpolated 2-D array "tt")
* tt()  : Section temperatures interpolated to 2-D grid
* twal  : Non-dimensional thickness of compartment walls
* wth   : Non-dimensional compartment width (Y-direction)
* x     : Non-dimensional X length of compartment to model
* xfrn1 : Starting 2-D, X coordinate of section to zoom in on
* xfrn2 : Ending 2-D, X coordinate of section to zoom in on
* xs()  : Non-dimensional grid locations
* xscn  : X location where Y-Z plane to be taken
* xss() : Non-dimensional staggered grid locations
* xtime : Non-dimensional time since fire ignition
* xx    : Non-dimensional length of 2-D X axis
* xxs() : 3-D grid points to be used as X coordinate in 2-D plot
* y     : Non-dimensional Y length of compartment to model
* yfrn1 : Starting 2-D, Y coordinate of section to zoom in on
* yfrn2 : Ending 2-D, Y coordinate of section to zoom in on
* yscn  : Y location where X-Z plane to be taken
* yy    : Non-dimensional length of 2-D Y axis
* yys() : 3-D grid points to be used as Y coordinate in 2-D plot
* zscn  : Z location where X-Y plane to be taken
